A short methodological note

Transparency International Corruption Perceptions Index (CPI) 2008

1. The CPI gathers data from sources that span the last two years. For the CPI 2008, this includes surveys from 2008 and 2007.
2. The CPI 2008 is calculated using data from 13 sources originated from 11 independent institutions. All sources measure the overall extent of corruption (frequency and/or size of bribes) in the public and political sectors and all sources provide a ranking of countries, i.e., include an assessment of multiple countries.
3. For CPI sources that are surveys, and where multiple years of the same survey are available, data for the last two years are included to provide a smoothing effect.
4. For sources that are scores provided by experts (risk agencies/country analysts), only the most recent iteration of the assessment is included, as these scores are generally peer reviewed and change very little from year to year.
5. Evaluation of the extent of corruption in countries is done by country experts, non resident and residents. In the CPI 2008, this consists of the following sources: Asian Development Bank, African Development Bank, Bertelsmann Transformation Index, Country Policy and Institutional Assessment, Economist Intelligence Unit, Freedom House, Global Insight and Merchant International Group. Additional sources are resident business leaders evaluating their own country; in the CPI 2008, this consists of the following sources: IMD, Political and Economic Risk Consultancy, and the World Economic Forum.
6. To determine the mean value for a country, standardisation is carried out via a matching percentiles technique. This uses the ranks of countries reported by each individual source. This method is useful for combining sources that have a different distribution. While there is some information loss in this technique, it allows all reported scores to remain within the bounds of the CPI, that is to say, to remain between 0 and 10.
7. A beta-transformation is then performed on scores. This increases the standard deviation among all countries included in the CPI and avoids the process by which the matching percentiles technique results in a smaller standard deviation from year to year.
8. All of the standardised values for a country are then averaged, to determine a country's score.
9. The CPI score and rank are accompanied by the number of sources, high-low range, standard deviation and confidence range for each country.
10. The confidence range is determined by a bootstrap (non-parametric) methodology, which allows inferences to be drawn on the underlying precision of the results. A 90 per cent confidence range is then established, where there is 5 per cent probability that

Last updated 19.8.2008

the value is below and 5 per cent probability that the value is above this confidence range.

11. Research shows that the unbiased coverage probability for the confidence range is lower than its nominal value of 90 per cent. The accuracy of the confidence interval estimates increases with a growing number of sources: for three sources, 65.3 per cent; for four sources, 73.6 per cent; for five sources, 78.4 per cent; for six sources, 80.2 per cent; and for seven sources, 81.8 per cent.

12. The overall reliability of data is demonstrated in the high correlation between sources. In this regard, Pearson's and Kendall's rank correlations have been performed, which provided average results of .78 and .63 respectively.
